VICTORIAN LOCAL GOVERNMENT AREA (LGA) DATA TABLES

Results are based on residential postcode of the affected family member / victim at the time of presenting to the hospital emergency department (VEMD), finalised intervention order application (court data) or family violence incident report (police data).

Each year the Victorian Family Violence Database project receives many requests for LGA level data and therefore produced this Appendix to provide information for the eleven-year period 1999-2010.

The data tables included in this Appendix provide a summary of key variables for each LGA (residential LGA of affected family member / victim). The tables are provided primarily to assist LGAs with information about family violence within their local area for planning purposes.

The data tables present overall summary counts and percentages for the LGAs, and are presented in alphabetical order. Many LGAs have small numbers of affected family members / incidents presenting in any given year. Caution must be used when analysing data for areas with small populations as a small shift of only a few cases across different categories can have a large impact on the percentage rates in any given year.

See Section 4.2 of the main report for a complete explanation of the data sets included in this Appendix.

Victorian Public Hospital Emergency Dataset (VEMD) - Overview

The importance of including the Victorian public hospital emergency department presentations for family violence (VEMD) data was highlighted in a report by the Monash University Accident Research Centre (Sherrard et al 1994) which identified that two per cent of all injuries to women presenting in emergency departments were considered human intended and inflicted by domestic partners. In addition, a small control study sample conducted with Victorian Injury Surveillance Systems (VISS)¹ data identified that 20 per cent of cases included in the VISS had a history of suspected injuries not detected prior to this study (Sherrard et al 1994, p. 76). This same report also estimated that 70 per cent of partner inflicted injuries are *undetected* in the emergency department (1994, p. 74).

¹ Victorian Injury Surveillance System data was collected between 1988 and 1996 and was limited to four major metropolitan hospitals and one large rural hospital (Western Hospital Footscray and Sunshine, Royal Children's Hospital, Preston and Northcote Community Hospital, Latrobe Regional Hospital and Royal Melbourne Hospital).

Detecting family violence cases through the emergency department is important for linking women otherwise not seeking assistance into intervention systems. Stark and Flintcraft (1991) highlight the importance in detecting these cases to enable early linkages into health, social service and justice systems to prevent escalation into more severe and longer term violence. Frank and Rodowski (1999) suggest that the patients in the emergency department, due to their state of crisis, may be more inclined to accept assistance that they might reject in other circumstances, and this may be the only opportunity an isolated victim may have to obtain access to assistance.

While medical professionals in the emergency departments are familiar with family violence injuries, officially recording this cause of injury is a relatively new category on the patient information forms and may involve a shift in thinking when collecting medical history. A recent study within the American Academy of Orthopaedic Surgeons (Bhandari et al 2008) revealed that the second most common injury women experienced related to family violence-caused musculoskeletal injuries (28%). However, 80 percent of orthopaedic surgeons responding to the survey believed that family violence was the cause in less than one per cent of their cases. Further, orthopaedic surgeons thought that questioning their patients about family violence would be an invasion of patient privacy.

In 2003-04 the Victorian public hospital system introduced a category of 'human intent injury' which identified injuries caused by a family member as *child neglect / maltreatment by parent / guardian* or *maltreatment / assault by partner*.

As referenced above, injuries due to family violence are believed to be under-reported in the VEMD human intent data field. Under-reporting occurs in this data set for several reasons:

- Injury cause is self-reported by patients and due to shame, or fear of repercussion from the perpetrator,² many patients with injuries inflicted through family violence may not readily nominate the cause
- Medical professionals utilise a great deal of caution when allocating the reason for injury unless clearly stated or admitted by the patient
- Self-inflicted injury as a result of, or in conjunction with, family violence can not be separated out for analysis in this report.

As the human intent data field identifying injuries associated with family violence is relatively new, analysis in this report has commenced with data from 2004-05 and continues to 2009-10.

² The results of two controlled studies conducted through the University of Queensland at the Royal Brisbane Hospital Emergency Department, between 1990 and 1993, revealed that one per cent of patients were accompanied by partners / parents who refused to leave their side and therefore could not be questioned about family violence (Roberts et al 1996).

(i) VEMD data are based on patients presenting to a Victorian public hospital with an injury identified as 'human intent' and the person causing injury is an immediate family member. (ii) LGA derived from residential postcode of patient at the time of presentation. Numbers are indicative as some postcodes cross LGA boundaries. (iii) Data reported are for the number of patients in separate presentations. Multiple presentations for the same person may be included.
